

# MEDICAL POLICY

<b>Medical Policy Title</b>	<b>Photodynamic Therapy for Malignant Disease</b>
<b>Policy Number</b>	<b>8.01.06</b>
<b>Current Effective Date</b>	<b>February 19, 2026</b>
<b>Next Review Date</b>	<b>February 2027</b>

Our medical policies are guides to evaluate technologies or services for medical necessity. Criteria are established through the assessment of evidence based, peer-reviewed scientific literature, and national professional guidelines. Federal and state law(s), regulatory mandates and the member's subscriber contract language are considered first in the determination of a covered service.

(Link to [Product Disclaimer](#))

## POLICY STATEMENT(S)

- I. Photodynamic therapy (PDT) with Photofrin is considered **medically appropriate** for **ANY** of the following indications:
  - A. Treatment of early-stage non-small-cell lung cancer (NSCLC) in patients who are ineligible for surgery and radiation therapy;
  - B. Reduction of obstruction and palliation of symptoms in patients with completely or partially obstructing endobronchial lesions;
  - C. Palliative treatment of obstructing esophageal cancer;
  - D. Treatment of Barrett's high-grade dysplasia (HGD) in patients who:
    1. are considered at high risk for adverse outcomes (morbidity and mortality) during prophylactic esophagectomy surgery; **and**
    2. decide on this treatment method, based on shared decision-making with their physician and understanding the actual risks and benefits of various treatment options;
  - E. Palliative treatment of unresectable cholangiocarcinoma as an adjunct to stenting.
- II. PDT with 5-aminolevulinic acid (5-ALA) topical preparation is considered **medically appropriate** for **EITHER** of the following indications:
  - A. Superficial and nodular basal cell skin cancer, only when surgery or radiation is contraindicated;
  - B. Bowen's disease (cutaneous squamous cell carcinoma in situ), only when surgery or radiation is contraindicated.
- III. PDT is considered **investigational** in the treatment of other types of malignancies, including but not limited to colon, rectal, pancreas, hepatocellular, mesothelioma, prostate, bladder, brain, head and neck cancers, soft tissue sarcoma and Barrett's esophagus (other than HGD, as stated above).
- IV. PDT with porfimer sodium (Photofrin) is contraindicated in patients with **ANY** of the following:
  - A. Known bone marrow suppression;

Policy Number: 8.01.06

Page: 2 of 8

- B. Porphyrin or known allergies to porphyrins;
- C. Existing tracheoesophageal or broncho-esophageal fistula;
- D. Tumors eroding into a major vessel;
- E. Esophageal or gastric varices or esophageal ulcers greater than one (1) cm in diameter.

### RELATED POLICIES

#### Corporate Medical Policy

- 7.01.01 Focal Therapies for Prostate Cancer Treatment
- 8.01.01 Extracorporeal Photochemotherapy/Photopheresis
- 8.01.21 Light and Laser Therapies for Dermatological Conditions
- 11.01.03 Experimental or Investigational Services
- 11.01.10 Clinical Trials

### POLICY GUIDELINE(S)

- I. A second laser treatment (with no additional Photofrin) can be given 96-120 hours after the first injection, preceded by debridement (via endoscopy) 48 hours after the initial light application.
- II. Patients may receive a second course of PDT (with Photofrin) a minimum of 30 days after the initial therapy. Up to three (3) courses of PDT (every 30 days) can be given.
- III. As pathologists do not always agree on differentiating between low- and high-grade dysplasia and between high-grade dysplasia and carcinoma in situ, in many cases, high-grade Barrett's dysplasia is confirmed by two pathologists with expertise in gastrointestinal pathology.

### DESCRIPTION

PDT is a cancer treatment method using intravenous injection of a photosensitizing agent (e.g., porfimer sodium, Photofrin) and exposure of tumor cells to a laser light source to cause cellular damage. The clearance of porfimer sodium occurs over a period of time (40-72 hours) in normal tissue; however, tumor cells retain porfimer for a longer period. Treatment of the tumor is the result of selective retention of porfimer and selective delivery of light.

PDT with Photofrin is a two-stage process. The first stage is the intravenous injection of Photofrin. Illumination with 630-nm wavelength laser light constitutes the second stage of therapy. The laser treatment induces a photochemical, not a thermal, effect. The photochemical reaction results in the release of toxic, singlet oxygen that causes tumor necrosis.

PDT should not be confused with extracorporeal photopheresis, which is the treatment of certain skin malignancies through the use of ultraviolet light irradiation of the patient's blood.

### SUPPORTIVE LITERATURE

Published studies have shown that PDT with Photofrin improves the quality of life (e.g., relief of

**Policy Number: 8.01.06**

**Page: 3 of 8**

dysphagia, improvement in dyspnea) and relieves obstruction by reducing tumor mass for those patients with obstructing tumors of the esophagus or endobronchial tree. For those patients with microinvasive NSCLC, not amenable to surgery or radiation, who were treated with PDT, reported tumor response rates (50-84%) and disease-free survival rates (2.7-4.1 years) are favorable. Studies investigating the neodymium-doped yttrium aluminum garnet (Nd:YAG) laser and PDT found that survival rates were comparable, and that PDT was technically easier to perform, more comfortable for patients, and caused fewer side effects (e.g., perforation).

In a systematic review and meta-analysis, investigators examined the effectiveness of PDT in the treatment of Bowen disease (BD) and cutaneous squamous cell carcinoma (cSCC) for clearance rate (CR) after 1 year. A total of 43 studies were included, enrolling 1,943 BD lesions and 282 SCC lesions. Pooled CRs for BD and SCC were 76 % (95 % CI: 71 % to 80%; I2 = 78.9 %) and 51 % (95 % CI: 35 % to 66 %; I2 = 85.7 %), respectively. The authors concluded that these findings supported the selective use of PDT for BD; however, patients should be advised of potential for recurrence. Moreover, these researchers stated that although PDT can be used for certain cases of cSCC, the high rate of treatment failure necessitates close surveillance for residual or recurrent disease; further studies are needed to justify the usage of PDT in the treatment of BD and cSCC (Yongpisarn 2022).

PDT has also been evaluated as an adjunct to stenting and drainage as a palliative treatment for unresectable bile duct cancer. Two pivotal yet small RCTs have demonstrated improvements in survival.

Ortner et al (2003) conducted a prospective, open-label, randomized multicenter study that aimed to compare PDT in addition to stenting with stenting alone in patients with NCC. A total of 39 patients with non-resectable cholangiocarcinoma were randomized to either PDT plus stenting (Group A, n =20) or stenting alone (Group B, n = 19). Investigators reported that the median survival was 493 days (95% CI, 276–710) in group A and 98 days (95% CI, 87–107) in group B (P < 0.0001). The investigators noted that PDT also improved biliary drainage and quality of life.

Zoepf et al (2005) conducted a randomized controlled study that investigated the influence of PDT on survival time in advanced bile duct cancer (BDC). A total of 32 patients with non-resectable cholangiocarcinoma were randomized. Light activation was performed in the patients assigned to PDT 48 hours after intravenous application of 2 mg/kg body weight of Photosan-3, an oligomer of hematoporphyrin that has been approved for use in the European Union but is not approved by the FDA. In the control group, patients were treated with stenting and drainage without PDT. The investigators stated that the PDT group and the control group were comparable due to age, gender, performance status, bilirubin level, and bile duct cancer stage. The investigators reported that the median survival time after randomization was 7 months for the control group and 21 months for the PDT group (p = 0.0109). The investigators noted that, in 50% of the initially percutaneously treated patients, they were able to change from percutaneous to transpapillary drainage after PDT.

Li et al (2023) stated that PDT is a promising treatment for non-muscle-invasive bladder cancer (NMIBC). In a systematic review, investigators examined the safety and effectiveness of PDT for the treatment of NMIBC. A total of 28 single-arm studies were included in the meta-analysis. For unresectable NMIBC, therapeutic PDT achieved CR in 68 % (95 % CI: 59 % to 77 %) of patients.

Page: 4 of 8

Among these CR cases, 71 % (95 % CI: 56 % to 85 %) and 38 % (95 % CI: 12 % to 64 %) had a RFS longer than 12 and 24 months, respectively. For tumor in situ (Tis) patients, the CR rate was 68 % (95 % CI: 56 % to 80 %), and 84 % (95 % CI: 48 % to 100 %) and 13 % (95 % CI: 1 % to 32 %) had a RFS longer than 12 and 24 months. For patients with resectable tumors, post-resection adjuvant PDT could provide a 12 and 24 months RFS in 81 % (95 % CI: 76 % to 87 %) and 56 % (95 % CI: 41 % to 71 %) of them. The complications were mostly mild and transient, including lower urinary tract symptoms and photosensitivity. The authors noted that although high-level evidence is still lacking, current studies suggested that both therapeutic and adjuvant PDT provided satisfying safety and effectiveness. Moreover, these researchers stated that as a promising option for NMIBC, PDT deserves further examination by future high-quality research.

Although PDT (using porfimer sodium or other photosensitizing agents) has been used in treatment of other cancers, all are either in Phase I or Phase II studies and have not yet been proven outside an investigational setting.

### PROFESSIONAL GUIDELINE(S)

The 2026 National Comprehensive Cancer Network (NCCN) Clinical Practice Guidelines in Oncology state that in patients with superficial basal cell carcinoma or squamous cell carcinoma in situ, therapies such as topical imiquimod, topical 5-fluorouracil (5-FU), or photodynamic therapy (PDT) may be considered, although cure rates are approximately 10% lower than for surgical treatment modalities. These options are also recommended for patients where surgery or radiation therapy is contraindicated or impractical.

Additionally, the NCCN Clinical Practice Guidelines (V.2.2025) Biliary Tract Cancers states, "Photodynamic therapy (PDT) is an ablative therapy that involves intravenous injection of a photosensitizing drug followed by selective irradiation with light of a specific wavelength to initiate localized drug activation and has been used for palliation in patients with extrahepatic cholangiocarcinoma (CCA). The combination of PDT with biliary stenting was reported to be associated with prolonged overall survival (OS) in patients with unresectable CCA in two small RCTs."

### REGULATORY STATUS

Photofrin (porfimer sodium) is the only photosensitizing agent with specific indications for use that has been approved by the U.S. Food and Drug Administration (FDA). It was approved in 2003.

The U.S. Food and Drug Administration (FDA) is responsible for ensuring the safety, efficacy, and quality of drugs sold in the United States. This includes both prescription and over-the-counter medications. Refer to the FDA Drug website. Available from: <https://www.fda.gov/drugs> [Accessed 2026 Jan 12]

The FDA maintains information for consumers and health professionals on new drug warnings and other safety information, drug label changes, and shortages of medically necessary drug products. Available from: [Drug Safety and Availability | FDA](#) [Accessed 2026 Jan 12]
