POLICY STATEMENT:

I. Based upon our criteria and assessment of the peer-reviewed literature, signal-averaged electrocardiography, has not been proven to be medically effective and is considered investigational for all indications, including but not limited to, the following:
   A. use for risk stratification regarding ventricular arrhythmia in patients following acute myocardial infarction;
   B. in patients with cardiomyopathy;
   C. in patients with syncope;
   D. as an assessment of success after surgery for arrhythmia;
   E. in the detection of acute rejection of heart transplants;
   F. as an assessment of efficacy of antiarrhythmic drug therapy; or
   G. in the assessment of success of pharmacological, mechanical, or surgical interventions to restore coronary artery blood flow.

II. Based on our criteria and assessment of the peer-reviewed literature, the Premier Heart 3DMP Computerized EKG System has not demonstrated a benefit to patient outcomes and is considered investigational as a technique of evaluating patients suspected of having coronary artery disease.

Refer to Corporate Medical Policy #2.01.45 regarding Microvolt T-Wave Alternans testing.

Refer to Corporate Medical Policy #11.01.03 regarding Experimental and Investigational Services.

POLICY GUIDELINES:

The Federal Employee Health Benefit Program (FEHBP/FEP) requires that procedures, devices or laboratory tests approved by the U.S. Food and Drug Administration (FDA) may not be considered investigational and thus these procedures, devices or laboratory tests may be assessed only on the basis of their medical necessity.

DESCRIPTION:

Signal-averaged electrocardiography (SAECG) is a non-invasive diagnostic test used to identify those patients that are at high risk of ventricular tachycardia, ventricular fibrillation, or sudden cardiac arrest. The signal-averaged ECG is a modification of a conventional ECG recording in which the signals are first amplified, then filtered, and finally averaged with the assistance of computer software to detect abnormalities, termed “ventricular late potentials” (VLP), that would otherwise be obscured by “background” skeletal muscle activity. VLP’s reflect aberrant, asynchronous electrical impulses arising from viable isolated cardiac muscle bordering an infarcted area and are thought to be responsible for ventricular tachyarrhythmias. Therefore, VLP’s as measured by SAECG, have been investigated as a risk factor for arrhythmic events in patients with a variety of cardiac conditions, including cardiomyopathy and prior history of myocardial infarction.
Since sudden cardiac death, whether from arrhythmias or pump failure, is one of the most common causes of death after a previous myocardial infarction, there is intense interest in risk stratification to guide therapy.

The Premier Heart Digital Database-Driven MultiPhase (3DMP) electrocardiograph (EKG) System, by Cardiotron, provides a computer analysis of digitalized 12-lead EKG waveform in the frequency domain (power spectral estimate) to aid in the early detection of significant coronary artery disease.

**RATIONALE:**

Signal-averaged ECG equipment requires FDA premarket approval to market the device as an instrument for recording low amplitude/high frequency components of the surface electrocardiogram for P wave analysis.

Signal-averaged electrocardiography has been thoroughly studied as a risk stratification tool for potentially fatal arrhythmias in patients with previous myocardial infarction. For the purpose of post-MI risk stratification, SAECG has been reported to have a sensitivity of 56-68%, a specificity of 74-81%, and positive predictive accuracy of about 20% for the occurrence of an event in the next 2 years.

Evidence demonstrates that SAECG has little clinical value in selecting patients who are at high risk for an arrhythmic event. Evidence is also lacking to demonstrate that the information could be used to alter treatment strategy and improve health outcomes. No prospective clinical studies have demonstrated the utility of this testing in improving clinical outcomes.

The 2010 AHRQ Technology Assessment, ECG-Based Signal Analysis Technologies, concluded there is currently little available evidence that pertains to the utility of ECG-based signal analysis technologies as a diagnostic test among patients at low to intermediate risk of CAD who present at the outpatient setting with the chief complaint of chest pain. The limited evidence that is available demonstrates proof of concept, particularly for the PRIME ECG and 3DMP devices. Further research is needed to better categorize the performance characteristics of these devices to determine in what circumstances, if any, these devices might precede, replace, or add to the standard ECG for the diagnosis of CAD among patients who present with chest pain in the outpatient setting.

The Premier Heart 3DMP EKG System, by Cardiotron, provides a computer analysis of digitalized 12-lead EKG waveform in the frequency domain (power spectral estimate) to aid in the early detection of significant coronary artery disease. The 3DMP system was cleared by the FDA in 2000 based on a 510(k) application that it was substantially equivalent as a programmable, diagnostic computer. The system is marketed as a noninvasive method of identifying patients with coronary artery disease. There are no evidence-based guidelines from national professional organizations that address clinical utility of 3DMP in evaluating patients suspected of having coronary artery disease.

In the 2016 Dinov et al study aimed to evaluate the utility of signal-averaged electrocardiogram (SAECG) for predicting outcomes after VT ablation. The main drawbacks (study limitations) were its small sample size (n=50) and the relatively short follow-up (median of 12 months). The authors stated that this study should be considered for the purpose of generating hypothesis. Although study results suggest that SAECG may be useful to assess the success after VT ablation, further well-designed studies are needed to determine its clinical utility for this patient population.
