**POLICY STATEMENT:**

Based upon our criteria and assessment of peer-reviewed literature:

I. **Stereotactic radiosurgery** has been medically proven to be effective and therefore **medically appropriate** for the following indications:
   A. Benign conditions:
      1. Arteriovenous malformations (less than 4 cm in diameter);
      2. Acoustic neuromas;
      3. Pituitary adenomas;
      4. Nonresectable, residual, or recurrent meningiomas;
      5. Craniopharyngiomas;
      6. Glomus jugulare tumor;
      7. Hemangioblastoma;
      8. Pineocytoma;
      9. Schwannoma;
      10. Cavernous malformations.
      11. Carotid body tumor;
      12. Glomus tympanicum;

   B. Primary tumors of the brain and spinal cord *that have been previously irradiated*.

   C. Primary spinal tumor with compression or intractable pain. (Literature doesn’t support – ASTRO recommends in clinical trial)

   D. Brain metastases under the following conditions:
      1. Initial treatment:
         a. Any number of lesions to be treated with no lesion greater than 3 cm; and
         b. Patient has a good performance status; and
         c. Systemic disease is limited and under control (or good options for systemic treatment are available); and
            all lesions can be encompassed in a single treatment plan; and
         d. The total volume of treated lesions should be considered safe to deliver SRS.
      2. Previous whole brain irradiation (WBRT):
         a. Patient has a good performance status; and
         b. Systemic disease is under control.
      3. No previous WBRT:
         a. Recurrence with 1-5 lesions; and
         b. More than 6 months has elapsed since RT; and
         c. Patient has a good performance status; and
         d. Systemic disease is under control.
E. The following indications when refractory to medical management and/or invasive neurosurgical treatment:
   1. Trigeminal neuralgia;
   2. Movement disorders (e.g., epilepsy, Parkinson’s disease, essential tremor, or familial tremor classifications with major systemic disease.

II. Stereotactic body radiation therapy (SBRT) has been medically proven to be effective and therefore medically appropriate for the following indications:
   A. Recurrent or residual nasopharyngeal carcinoma at primary site when radiation therapy treatments such as three-dimensional conformal or IMRT cannot be utilized;
   B. Spinal or vertebral body tumors (metastatic or primary) in patients who have received prior radiation therapy;
   C. Inoperable stage I or II Non-small cell lung cancer (NSCLC);
   D. Pancreas:
      1. Preoperative (neoadjuvant resectable or borderline resectable), following a minimum of 2 cycles of chemotherapy, and restaging in which there is no evidence of tumor progression; or
      2. Definitive treatment for medically inoperable or locally advanced, following a minimum of 2 cycles of chemotherapy and restaging when there is no evidence of tumor progression, and the disease volume can be entirely encompassed in the radiation treatment volume; or
      3. Postoperative (adjuvant) when there is residual gross disease or positive microscopic margins that can be entirely encompassed in the radiation treatment volume;
      4. For palliative situations SBRT is considered not medically necessary.
   E. Primary Liver Cancer (Hepatocellular Carcinoma [HCC]) in the definitive setting to treat concurrently one or more tumors when there is evidence of the ability to protect an adequate volume of uninvolved liver.
   F. Any of the following neoplasms presenting with 1 to 3 metastases in the synchronous setting when local control is expected and treatment of the metastases may result in an increased disease-free interval and possible survival:
      1. For an individual with non-small cell lung cancer who:
         a. has had or who will undergo curative treatment of the primary tumor (based on T and N stage) and
      2. For an individual with colorectal cancer who:
         a. has had or who will undergo curative treatment of the primary tumor and
         b. whose metastases are in the lung or liver and
         c. for whom surgical resection is not possible.
   G. Any of the following neoplasms where the primary tumor was previously controlled and metachronous metastases have presented under all of the following circumstances:
      1. Clinical presentation of 1 to 3 metastases of the adrenal gland, lung, liver, or bone when the following criteria are met:
         a. histology is non-small cell lung, colon, breast, sarcoma, renal cell or melanoma;
         b. disease free interval of greater than one (1) year from the initial diagnosis;
         c. primary tumor received curative therapy and is controlled;
         d. no prior evidence of metastatic disease (cranial or extracranial); or
      2. An individual with sarcoma, renal, or melanoma metastases who meets the following criteria:
         a. disease free interval of > 1 year from the initial diagnosis; and
         b. primary tumor received curative therapy and is controlled; and
         c. no prior evidence of metastatic disease.
      3. An individual with breast cancer who meets the following criteria:
         a. has 1 to 3 sites of disease limited to the lung, liver, or bone;
Proprietary Information of Excellus Health Plan, Inc.

b. disease free interval of greater than one (1) year from the initial diagnosis;
c. primary tumor received curative therapy to the primary tumor.

4. SBRT to greater than 3 sites other than those indications listed above is considered experimental/investigational.

H. Prostate cancer; clinically localized disease when used as definitive treatment low-, intermediate-, and high-risk and negative bone scan within the last 6 months (bone scans not recommended for patients with low risk prostate cancer – PSA less than 10 and GS less than 7 and stage 1c/2a). \ 
I. Locally recurrent soft tissue sarcoma that is within or immediately adjacent to an area that has received radiation treatments as part of the primary management.

III. Stereotactic body radiation therapy has not been medically proven to be effective and is considered not medically necessary for extrahepatic bile duct cancer (cholangiocarcinoma), gall bladder cancer.

IV. Stereotactic radiosurgery has not been medically proven to be effective and is considered not medically necessary for the treatment of chronic pain.

V. Stereotactic body radiation therapy has not been medically proven to be effective and is considered investigational as a boost for prostate cancer.

Refer to Corporate Medical Policy #6.01.11 regarding Proton Beam Radiation.
Refer to Corporate Medical Policy #6.01.24 regarding Intensity Modulated Radiation Therapy (IMRT).
Refer to Corporate Medical Policy #7.01.23 regarding Deep Brain Stimulation.
Refer to Corporate Medical Policy #11.01.03 regarding Experimental or Investigational Services.

POLICY GUIDELINES:
The Federal Employees Health Benefit Program (FEHBP/FEP) requires that procedures, devices or laboratory tests approved by the U.S. Food and Drug Administration (FDA) may not be considered investigational and thus these procedures, devices or laboratory tests may be assessed only on the basis of their medical necessity.

DESCRIPTION:
Stereotactic radiosurgery (SRS). SRS is a method of delivering high doses of ionizing radiation to small targets. This technique differs from conventional radiotherapy, which involves exposing large areas of tissue to relatively broad fields of radiation over a number of sessions. SRS entails delivering highly focused convergent beams in a single session so that only the desired target is radiated, sparing adjacent structures.

Stereotactic body radiation therapy (SBRT). As stated in the guideline developed by the American College of Radiology (ACR) and the American Society for Radiation Oncology (ASTRO), stereotactic body radiation therapy (SBRT) is an external beam radiation therapy method used to very precisely deliver a high dose of radiation to an extracranial target within the body, using either a single dose or a small number of fractions. Specialized treatment planning results in high target dose and steep dose gradients beyond the target. The ability to deliver a single or a few fractions of high-dose ionizing radiation with high targeting accuracy and rapid dose falloff gradients encompassing tumors within a patient provides the basis for the development of SBRT. SBRT can be applied using noninvasive or minimally invasive stereotactic localization and radiation delivery techniques. It requires significantly improved delivery precision over that required for conventional radiotherapy. Specialized imaging techniques may be required to either limit or compensate for target movement during treatment planning and delivery.

RATIONALE:
The addition of stereotactic radiosurgery as a treatment regimen for intracranial masses less than 4 cm in diameter (e.g., gliomas, brain metastases, and meningiomas) has improved health outcomes by providing local tumor control...
and increasing survival rates. Radiosurgery in patients with lesions over 4 cm is associated with increased complications (e.g., radionecrosis, CNS toxicity) and lowers probability of reaching effective radiation doses.

Radiosurgery performed on inoperable arteriovenous malformations (AVM’s) with diameters less than 4 cm have found to have obliteration rates up to 94%.

Stereotactic radiosurgery for trigeminal neuralgia refractory to medical management has similar outcomes compared to alternative treatments (e.g., microvascular decompression), is the least invasive non-pharmacologic treatment and is associated with less complications (facial paresis, pain recurrence) than alternative treatments. Outcomes of Gamma radiosurgery for acoustic neuroma include local tumor control, preservation of hearing and facial nerve function.

While data is minimal investigating whether the cumulative higher radiation provides improved patient outcomes such as medium survival or quality of life for patients with malignancies, it is felt fractionated radiosurgery (stereotactic radiotherapy) provides a palliative benefit and can offer a chance of prolonged survival. Its use for the treatment of acoustic neuroma increases the preservation of facial nerve function and decreases hearing loss associated with alternative treatments. A single-institution study reported outcomes of single fractions vs. fractionated LINAC-based stereotactic radiosurgery in 129 patients with acoustic neuromas. With an average follow-up of 33 months, there was no difference in outcome in terms of local tumor control, facial nerve preservation, and hearing preservation.

Small case series examined the role of gamma knife radiosurgery in the treatment of refractory movement disorders, although radiofrequency ablation or deep brain stimulation would be considered the gold standard therapies for this indication. The ordering provider must certify that the usual and customary treatments outlined above would not be successful in managing the member’s condition.

Several small prospective studies of stereotactic radiosurgery of spinal cord lesions, metastatic and primary, conclude that radiation-induced toxicity is minimal with axial and radicular pain improvement as high as 96%. Major benefits are relatively short treatment time in an outpatient setting combined with potentially better local control of the tumor with minimal risk of side effects. Stereotactic technique also allows for the treatment of lesions previously irradiated with conventional external beam irradiation.

Literature has increased regarding stereotactic radiosurgery/radiotherapy of other extracranial sites. Numerous studies address SRS/SRT of the lung and liver (for both primary and metastatic lesions), renal cell carcinoma (for both primary and metastatic lesions), pancreas, adrenal glands, and for oligometastases. These studies are generally of small sample size but show that the control rate is similar to the control rate for brain metastases (e.g. over 90%).

Literature is active with respect to the use of SRT for treatment of low to intermediate risk prostate cancer. Studies are small but improvements in quality of life and mild (grade I-II) toxicities have been reported. SBRT using a hypofractionation regimen for treatment of prostate cancer has been suggested as a more cost-effective alternative to IMRT because the treatment time is shorter, it utilizes resources more effectively, and this regimen is more convenient to the patient with less time away from work and savings in transportation and housing if the treatment center is located away from the patient’s home. Preliminary modeling comparing costs of IMRT, radical prostatectomy and SBRT show SBRT is more cost-effective. However the models assume the efficacy, treatment-related toxicities and costs of treating the toxicities are the same for all treatment modalities. Since the period of follow-up is currently much shorter for SBRT than the other modalities, there is uncertainty of the frequency and severity of late effects. Thus the current models may show a greater difference in costs and savings than those reported once SBRT late effects are known. Current studies all recommend larger study sizes and longer follow-up to determine late toxicities of treatment of prostate cancer using hypofractionated stereotactic body radiation therapy. Recommendations on SBRT for prostate cancer treatment after the 2010 ASTRO conference concluded that SBRT for prostate cancer is technically feasible with little reported morbidity. Very early results of limited statistical power suggest that the initial PSA response is equivalent to that observed with conventional fractionated RT with follow up beyond 5 years but less than 10 yrs. SBRT for low and intermediate risk prostate cancer in selected and well-informed patients is considered an acceptable first line of treatment. However comparative studies are still needed.
Literature regarding stereotactic radiosurgery/radiotherapy as first-line treatment of meningioma consists of prospective and retrospective case series that conclude SRS provides high rates of tumor growth control or regression in patients with benign meningiomas with low risk, and in patients with cavernous sinus meningioma.

Due to a lack of clinical trials, there is insufficient evidence to permit conclusions about health outcomes for the treatment of chronic pain.
