POLICY STATEMENT:

I. Based upon our criteria and review of peer reviewed literature, virtual colonoscopy is considered a **medically appropriate** option for screening in average-risk individuals ages 50 to 75.

II. Based upon our criteria and review of peer reviewed literature, virtual colonoscopy is considered a **medically appropriate** option for diagnosis as follows:
   
   A. In those patients in whom a conventional endoscopic colonoscopy of the entire colon is incomplete due to an inability to pass the colonoscope proximally. Failure to advance the colonoscope may be secondary to an obstructing neoplasm, spasm, redundant colon, chronic diverticular disease, extrinsic compression or aberrant anatomy/scarring from prior surgery; or
   
   B. In those patients with concurrent medical conditions for whom conventional colonoscopy is contraindicated. Medical contraindications may include but are not limited to coagulopathy, intolerance to sedation, elderly greater than or equal to 80 years of age, and recent (within the last 60 days) myocardial infarction (MI).

III. Based upon our criteria and review of peer-reviewed literature, **computer-aided detection (CAD)** to identify and mark regions of interest with virtual colonoscopy has not been medically proven to be effective and is considered investigational.

Refer to Corporate Medical Policy #11.01.03 regarding Experimental and Investigational Services.

Refer to Corporate Medical Policy #11.01.10 regarding Clinical Trials.

POLICY GUIDELINES:

I. **Contraindications** for a virtual colonoscopy include but are not limited to:
   
   A. Active Crohn’s disease, ulcerative colitis, inflammatory bowel disease or diverticulitis; or
   
   B. Total hip replacement (metal in prosthesis may cause CT scan artifacts); or
   
   C. Recent surgery; or
   
   D. Pregnancy; or
   
   E. Severe pain or cramps on day of examination.

II. Screening using virtual colonoscopy for colorectal cancer is recommended every 5 years in average-risk individuals ages 50 to 75 (average risk is defined as no history of adenoma and inflammatory bowel disease and negative for first degree family history of colorectal cancer).

III. The Federal Employee Health Benefit Program (FEHBP/FEP) requires that procedures, devices or laboratory tests approved by the U.S. Food and Drug Administration (FDA) may not be considered investigational and thus these procedures, devices or laboratory tests may be assessed only on the basis of their medical necessity.

DESCRIPTION:

Virtual colonoscopy, also known as CT colonography, is a non-invasive imaging technique for examination of the colonic lumen that involves the generation of both 2-dimensional and 3-dimensional views of the colon and rectum using data derived from helical computed tomography, involving thin-section helical computed tomography (CT) to generate high-resolution 2-dimensional axial images of the colon. Two- or three-dimensional images, which resemble the
endoluminal images obtained with conventional endoscopic colonoscopy, are then reconstructed offline. Virtual colonoscopy has been investigated as an alternative to conventional endoscopic colonoscopy specifically as an alternative screening technique for colon cancer.

While virtual colonoscopy requires a full bowel preparation similar to conventional colonoscopy, no sedation is required and the examination is less time consuming. However gas insufflation of the intestine, which may be uncomfortable to the patient, is required and interpretation of the images is a separate process. When polyps are detected with virtual colonoscopy, treatment requires that patients undergo a subsequent endoscopic colonoscopy, which may require another bowel preparation.

RATIONALITY:
Reformatting software systems for interpretation of virtual colonoscopy have been approved by the FDA, such as but not limited to the Viatronix V3D-colon virtual colonoscopy system (Viatronix, Inc., Stonybrook, NY) cleared for marketing by the FDA via the 510(k) process April 19, 2004, for use as a screening tool in detecting colon cancer. Computer-aided detection (CAD) for virtual colonoscopy has not yet received FDA approval.

Results of available studies indicate that CT colonography (CTC) (virtual colonoscopy) can have relatively high sensitivity and specificity for detection of cancerous colorectal lesions that are at least 6-10 mm in diameter, with lower sensitivity for precancerous, smaller, and flat lesions. The sensitivity of CTC in published studies is heterogeneous, varying widely, but improving as polyp size increases. CTC specificity in published studies is homogeneous, also improving as polyp size increases. CTC does not permit removal of lesions during the procedure as can be done during conventional colonoscopy. Results from the National CT Colonography Trial, ACRIN-6664 (NCT00084929), which is an interventional, screening, open-label trial of 2,600 participants who had a CTC followed by their scheduled colonoscopy showed that for large adenomas and cancers, the mean (±SE) per-patient estimated sensitivity, specificity, positive and negative predictive values, and area under the receiver-operating-characteristic curve for CT colonography were 0.90±0.03, 0.86±0.02, 0.23±0.02, 0.99±0.01, and 0.89±0.02, respectively. The sensitivity of 0.90 (i.e., 90%) indicated that CT colonography failed to detect a lesion measuring 10 mm or more in diameter in 10% of patients. The per-polyp sensitivity for large adenomas or cancers was 0.84±0.04. The per-patient sensitivity for detecting adenomas that were 6 mm or more in diameter was 0.78. These findings support and extend previously published data regarding the role of CT colonography in screening patients with an average risk of colorectal cancer.

Since CTC requires bowel preparation and bowel insufflation, it is unclear if patient acceptance will be much higher than for conventional colonoscopy. Preliminary evidence suggests that CTC can detect colorectal polyps and tumors in sections of the colon that cannot be evaluated by conventional colonoscopy due to poor bowel preparation, an unsuitable colon configuration, an obstructing neoplasm, or poor patient tolerance. CTC can also detect some extracolonic abdominal disorders that cannot be detected using conventional colonoscopy, however clinical evidence does not indicate the impact of CTC extracolonic findings on patient management and disease outcomes.

There is no direct evidence as to whether CTC improves health outcomes. Nor does the current evidence allow conclusions as to the comparative efficacy of CT colonography and other colon cancer screening techniques.

In May 2008 the American Cancer Society, American College of Radiology, and U.S. Multi-Society Task Force on Colorectal Cancer issued joint guidelines for screening and surveillance for early detection of colorectal cancer and adenomatous polyps. The guidelines outline a variety of options for colorectal screening, divided into two categories: (1) fecal tests to detect colorectal cancer and (2) structural exams to detect adenomas and colorectal cancer. CTC is recommended for colorectal screening every five years as a test to detect adenomatous polyps and cancer.

The American College of Physicians Guidance Statement recommends that physicians perform an individualized assessment of risk for colorectal cancer in all adults. Because the currently available colorectal cancer screening tests are believed to be similarly efficacious, shared decision making is important when selecting a screening test. Clinicians should discuss the benefits, harms, effectiveness, safety, and costs of the options available to screen for colorectal cancer. Computed tomography colonography is an option for screening in average-risk patients older than 50 years and is supported by some guidelines. Recommended screening interval for CTC is every 5 years.
The U.S. Preventative Services Task Force updated their recommendations for colon cancer screening in 2016. Instead of emphasizing specific screening approaches, the USPSTF has instead chosen to highlight that there is convincing evidence that colorectal cancer screening substantially reduces deaths from the disease among adults aged 50 to 75 years and that not enough adults in the United States are using this effective preventive intervention. CT Colonography as a screening modality is recommended every 5 years. Evidence for assessing the effectiveness of computed tomography (CT) colonography is limited to studies of its test characteristics. Computed tomography colonography can result in unnecessary diagnostic testing or treatment of incidental extracolonic findings that are of no importance or would never have threatened the patient’s health or become apparent without screening (ie, overdiagnosis and overtreatment). Extracolonic findings are common, occurring in about 40% to 70% of screening examinations. Between 5% and 37% of these findings result in diagnostic follow-up, and about 3% require definitive treatment. As with other screening strategies, indirect harms from CT colonography can also occur from follow-up colonoscopy for positive findings. Radiation-induced cancer is a potential long-term concern with repeated use of CT colonography. No studies directly measured this risk, but radiation exposure during the procedure seems to be low, with a maximum exposure of about 7 mSv per examination.

Computer-aided detection (CAD) for virtual colonoscopy/CT colonography is still under active development. Recent studies have been small and have found that use of CAD with an inexperienced reader is no better than interpretation by an experienced reader alone. Use of CTC with or without CAD for nonpolypoid lesions showed a sensitivity of 90% for both CAD and human readers. However the sensitivity for nonpolypoid adenomas, nonadenomatous and noncancerous lesions to be 66% or less for human readers and 55% or less for CAD. CTC may be useful for detecting nonpolypoid adenocarcinomas but is limited in detecting other nonpolypoid pathology.

**CMS COVERAGE FOR MEDICARE PRODUCT MEMBERS**

CMS has proposed a national coverage determination (NCD) for the use of screening computed tomography colonography (CTC) for colorectal cancer. There is a national coverage determination (NCD) for colorectal cancer screening tests. Screening computed tomographic colonography (CTC) is considered non covered, effective May 12, 2009. [https://www.cms.gov/medicare-coverage-database/details/ncd-details.aspx?NCDId=281&ncdver=5&bc=AgAAgAAAAAAA%3d%3d&](https://www.cms.gov/medicare-coverage-database/details/ncd-details.aspx?NCDId=281&ncdver=5&bc=AgAAgAAAAAAA%3d%3d&)
